Exchange bias (EB) has been recently observed in NiMn-based Heusler bulk alloys. It has been shown that it results from coexisting ferromagnetic (FM) and antiferromagnetic (AFM) phases. We report a relatively large EB effect observed for the first time in Ni-Mn-Sn thin films with different microstructure and composition. The thin film structures prepared by magnetron sputtering comprise: a MgO/Ni\textsubscript{50}Mn\textsubscript{36}Sn\textsubscript{14} (200 nm) off-stoichiometric epitaxial film with clearly visible martensitic transformation at $T \approx 125$ K (sample A), a Si/Ni\textsubscript{50}Mn\textsubscript{43}Sn\textsubscript{7} (100 nm) film phase decomposed into (AFM) Ni\textsubscript{50}Mn\textsubscript{50} and (FM) Ni\textsubscript{50}Mn\textsubscript{25}Sn\textsubscript{25} (sample B), and a Si/NiMn(50 nm)/Ni\textsubscript{50}Mn\textsubscript{25}Sn\textsubscript{25} (30 nm) bilayer with AFM/FM interface but without any EB near room temperature (sample C). Despite the samples differ markedly in both microstructure and composition the substantial EB is present at low temperature region $4 < T < 80$ K. The highest EB effect is observed in phase decomposed sample B with overdeveloped AFM/FM interfaces. EB decreases with increasing $T$ approximately as $H_{EB}(T) \propto H_{EB}(4K)/T$. $H_{EB}(4$ K) amounts to 190 Oe, 65 Oe and 60 Oe for sample B, A and C, respectively. Blocking temperature where the EB vanishes is 40, 50 and 80 K for sample A, C and B, respectively. The results suggest that the role of AFM/FM interfaces is small (but not negligible) in formation of EB in Ni-Mn-Sn Heusler alloy films and EB is rather related to AFM/FM interactions in nanoscale.
